#### **ABSTRACT**

In April 1964 study was begun of the ocean floor at the proposed site for emplacing Submersible Test Unit II (STU II) series to determine whether the floor would provide a suitable foundation for the STUs. Eight sediment cores were taken to determine the engineering properties of the sediments in an area approximately 2 miles square in the vicinity of 34° 05.5°N, 120° 43.0°W, some 14 miles west of San Miguel Island, California. In addition, a bathymetric chart of the area was constructed using data from the precision depth recorder and navigational instruments aboard the USS Molala. Laboratory tests were conducted on core samples and computations of bearing capacity and settlement were made for the area with the resulting data. The calculated average bearing capacity was 300 pounds per square foot. The applied load of the STU was approximately 110 pounds per square foot. The calculated total settlement was 1.7 inches.

The test results were analyzed statistically to determine the relationships
(1) between vane shear strength and depth below the sediment surface, liquid limit, and median particle diameter; and (2) between bulk wet density and vane shear strength and sensitivity. The results indicate the correlations are satisfactory for use in site reconnaissance and site selection studies.

#### INTRODUCTION

The Naval Civil Engineering Laboratory is studying the effects of the deep ocean environment on construction material 1 in conjunction with the deep ocean engineering program. To accomplish this task, submersible test units (STUs)<sup>2</sup> have been designed and placed in selected locations off of the Santa Barbara Channel islands along the coast of southern California. In support of this project, the ocean floor features at these sites have been studied to determine the suitability of the sites as foundations for the STUs. This report presents the results obtained from the investigation of the STU-II site, which is the shaded area shown in Figure 1. This study began in April 1964.

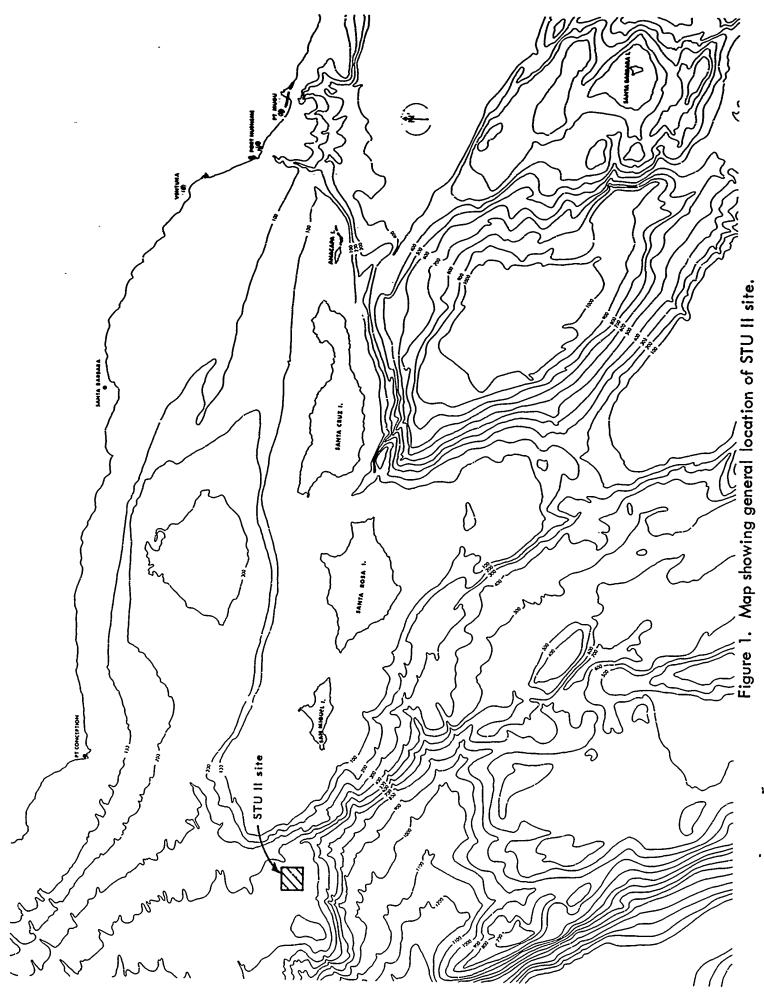

This report covers (1) the sampling and testing procedures used in this study of marine sediments, (2) the results of tests and foundation analysis, and (3) a statistical analysis of the relationships between (a) vane shear strength and bulk wet density, and (b) various laboratory-measured properties of the sediments.

#### SAMPLING PROCEDURE

The USS Molala was used for all the bathymetric survey and sampling phases at sea. The precision depth recorder and the navigation equipment aboard the vessel were used in the bathymetric survey phase. All locations were referenced to Richardson's Rock by using radar and dead reckoning methods of positioning.\* The detailed bathymetric chart of the STU-II site as shown in Figure 2 was then constructed from the data obtained from this survey.

During the coring phase, the vessel was maneuvered into the preselected position of each core and all engines were secured. The assembled coring apparatus was then lowered until a sample was obtained, at which time the location of the vessel, water depth, and other identifying data were logged. The vessel was not equipped for maintaining precise positions in the open sea; therefore, some drift of the vessel occurred during the sampling interval. The coring phase continued until eight cores (Table 1) were secured. The entire coring operation was accomplished within an elapsed time of 10 hours. All of the sediment cores were obtained using a Ewing-type gravity coring apparatus (Figure 3) for which characteristic data is shown in Table 2.

<sup>\*</sup>The LORAC positioning system was not available at NCEL at the time of this study.

<sup>1/</sup> From Reference 3.

The equipment and sampling capabilities to preserve in-situ conditions such as pore pressure, temperature, and salinity of the samples were not available at the time of this study. However, the samples were guarded against other physical disturbances. The core samples were stored vertically on board the vessel in a honeycomb compartment box, each core in an individual cell. When the samples were delivered to NCEL, they were stored in a controlled-humidity room until the physical testing could be conducted about a week later.

#### TESTING EQUIPMENT AND PROCEDURES

These cores were tested in the laboratory using soil-testing methods described by References 4, 5, 6, 7, and 8. The general routine laboratory procedure that each sample was subjected to is described by Smith and Hironaka. The first step in the testing routine was removal of a 3-inch interval from a sample by the sectioning method described by Smith and Nunes. The test sequence which this section and the other sections tested\* then underwent was:

- 1. Bulk wet density
- 2. Vane shear strength (undisturbed sample)
- 3. Original water content
- 4. Vane shear strength (remolded sample)
- 5. Atterberg limits
- 6. Specific gravity
- 7. Grain-size analysis
- 8. Carbonate organic carbon analysis

Special equipment used in the tests was the vane shear testing apparatus, the air-comparison-type pycnometer for specific gravity determination, and the carbon determinator for carbonate and organic carbon analysis. The vane shear testing apparatus (Figure 4) developed by Smith\*\* is unique because the complete record of the shear test is automatically recorded. The sample is placed on the pedestal which is driven by a synchronous motor geared to obtain a constant angular velocity of 1 revolution per hour. The vane is then introduced into the sample and the pedestal rotation initiated. The calibrated torque output from the vane is then measured through an instrumented cantilever reed system and recorded on a constant-velocity chart. A complete history of the shear failure is therefore recorded on this chart.

<sup>\*</sup>Every other 3-inch interval was tested.

<sup>\*\*</sup>U. S. Naval Civil Engineering Laboratory. Continuous recording vane shear apparatus, by R. J. Smith, Ph D. Port Hueneme, Calif. (unpublished manuscript)

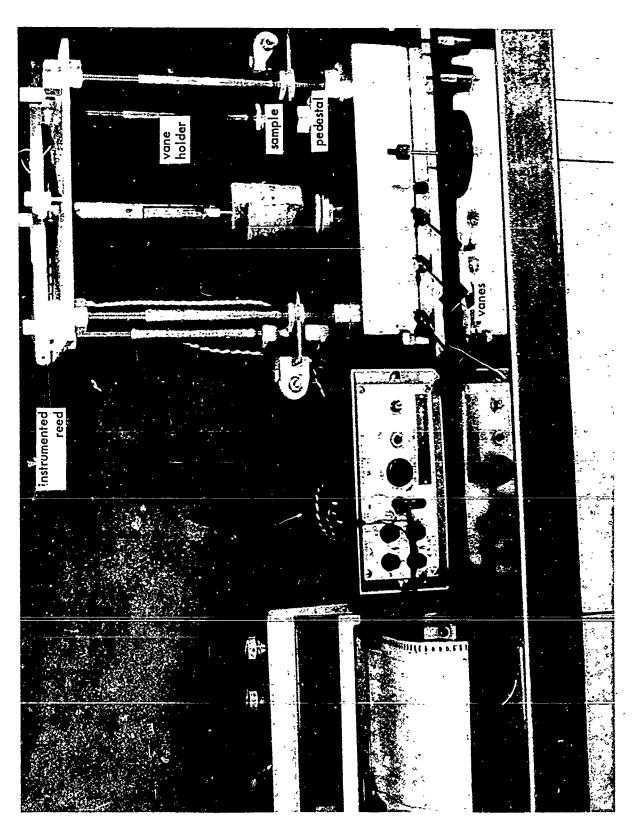

Figure 4. Vane shear apparatus with sample being tested.

The air-comparison-type pycnometer shown in Figure 5 was used for all the specific gravity determinations. This pycnometer has two chambers (designated as measuring and reference) calibrated to a known volume. A known weight of dry sample was subjected to a partial vacuum in the measuring chamber. At this pressure, the change in volume of the measuring chamber relative to the reference chamber was taken as the volume of the solid particles. The volumes of the solid particles measured by this method appear to be closely camparable to those measured by the accepted ASTM<sup>4</sup> method. This method offers the advantage of being rapid in that each test can be accomplished in approximately 5 minutes.

Carbon content determinations were made with a carbon determinator (Figure 6) utilizing an induction furnace and an oxygen combustion medium. This type of apparatus is commonly used in industry to measure the carbon content of structural steel and other metals. Each sample was divided into two parts. Approximately 1/2 gram of sample from the first part was weighed and placed in a combustion crucible, treated with hydrochloric acid to remove the carbonate carbon, rinsed with distilled water, and dried in an oven. Approximately the same amount from the second part was weighed and placed in a second crucible. Tin-coated copper and iron chip accelerators were then placed in each crucible and the separate tests conducted.

The visual observation procedures which require some explanation are the color determination, core logging, and microscopic analysis. Color determinations were made by visual comparison with a rock color chart. This determination was done immediately upon removal of each 3-inch section of a sample. The intermediate sections which were not tested in the above procedures were split longitudinally to obtain additional information for the core log. The microscopic analysis of the plus 325-mesh fraction obtained from the grain size analysis was accomplished using a binocular microscope. The core log and the microscopic analysis were made after the above tests.

#### DATA REDUCTION METHODS AND RESULTS

Data reduction was done by computer methods described in detail by Hironaka.\* Three basic computer programs for the IBM 1620 Mode? II at NCEL were used to reduce all test data. The results of the data reduction are presented in Tables A-1 through A-8 of Appendix A. The data in each table represents one core sample. The values presented are self-explanatory in most cases.

Methods for determining values for liquid limit, compression index, carbonate content, organic content, and sediment type require some explanation, since there are other methods for obtaining these values. By using the familiar liquid-limit

9

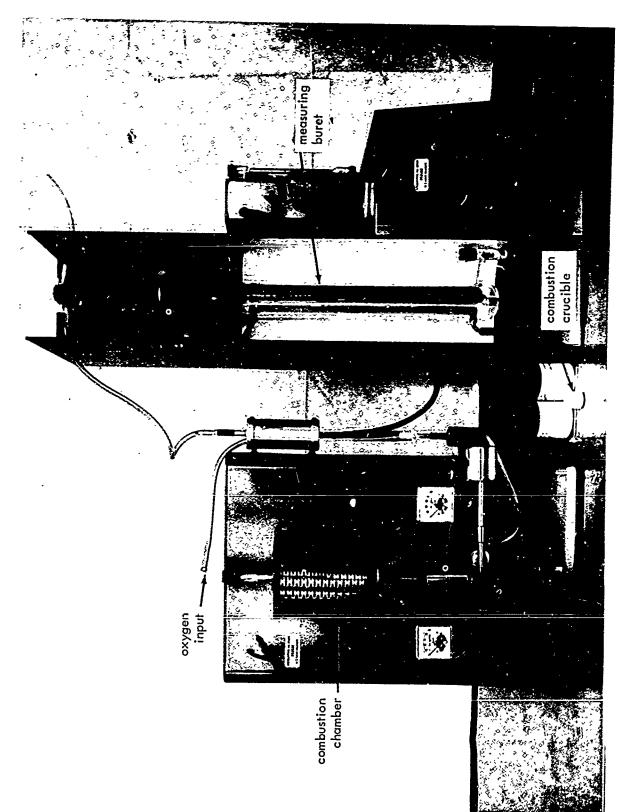

Figure 6. Carbon determinator used in carbonate - organic carbon analysis.

mechanical device, the liquid limit was determined by the one resint method as described by Joslin and Davis. <sup>12</sup> An approximation of the compression index was made by using the relationship <sup>13</sup>

$$CI = 0.009(LL - 10)$$

where CI = compression index

LL = liquid limit

Carbon content in the form of calcium carbonate and organic matter was determined by the following relationships:

Carbonate content (%) = (% carbon, untreated sample minus % carbon, treated sample) x 8.3

Organic content (%) = (% carbon, treated sample)  $\times 1.7$ 

The gravimetric factor, 8.3, was obtained from the relationship between the atomic weight of carbon and the molecular weight of calcium carbonate. The factor 1.7 was obtained from Reference 14. Sediment type was determined from the usual trilineal plot of sand-silt-clay percentages modified by Shepard <sup>15</sup> for marine sediments. All other test results shown in Tables A-1 through A-8 are derived by the standard computational methods used in soil investigations.

Dating of the samples was done by paleontological methods by Carson.\* The microfaunas and lithology of all eight samples were reported to be very similar. An exact date could not be assigned, however, because (1) the samples were from an off-shore marine environment in which no overlying sediments were present that could be classified as Recent, (2) the foram nifera all represented living species, and (3) the beds were not folded. However, for the environmental conditions at the location of the samples (depth of water, 2,000 to 4,000 feet; temperature, 3° to 5°C), the age of the sediments could be from early Pliocene to Pleistocene.

#### DISCUSSION

Test Results

The test results fall into two basic categories. The first category, the observed values of the sample, includes color, odor, microscopic analysis, and the features described in the core log. The second category, the measured and computed values of the sample, includes those values that are obtained from the laboratory testing procedures listed earlier.

<sup>\*</sup> Offshore Punch Core Samples, by Carlton M. Carson, Consulting Paleontologist. Ventura, Calif., April 1966 (Memo to R. J. Smith).

In observed values, the samples were quite similar. The color variation was narrow, ranging from a moderate olive brown (5Y 4/4) to an olive gray (5Y 3/2). 11 Four of the core samples (MH-1, 4, 7, 8) tended to become darker to olive gray with depth of the sample. The other four samples were somewhat uniform moderate olive brown. Hydrogen sulfide odor was present throughout the samples. No degree of difference in intensity of the odor was noticed.

In the microscopic analysis it was observed that the plus-325-mesh fraction contained principally glauconite, quartz, and foraminifera (both planktonic and benthonic). Glauconite was the primary constituent in the coarse fraction of samples MH-1, 2, 3, and 4, while quartz was the primary constituent in samples MH-5, 6, and 7. Sample MH-8 had approximately an equal amount of glauconite and quartz. There appears to be an abrupt change in glauconite concentration between the above two groups of samples. This may be indirectly related to the high bottom currents (maximum 0.4 knot — average 0.1 knot at 4 feet above the ocean floor recorded during STU II-1 exposure) and the associated temperature and salinity differences between the water masses merging in this vicinity. This abrupt change in glauconite concentration has also been observed by Wright,\* who has conducted extensive research in this general area. Benthonic and Planktonic foraminifera were present in minor amounts in all of the samples. Samples MH-5 and 6 contained a larger percentage of foraminifera than the others.

In the core-logging process, there were no observed features that would be detrimental to the stability of the structure. There were no weak layers that could be classified as being the seat of settlement observed in the sediment columns retrieved. Samples MH-2 and 4 had a layer of pebbles at the base which stopped the passage of the corer.

In measured and computed values, the samples were quite similar. Figures B-1a to B-7b of Appendix B are plots of the results. Bulk wet density, vane shear strength of undisturbed samples, vane shear strength of remolded samples, and dry density appear to increase with depth in the core. Deviation of these values from this trend towards the base of the core is probably due to disturbance during the coring process rather than a stratigraphic condition. The values for sensitivity, water content, void ratio, porosity, and saturated void ratio, appear to decrease with depth in the core. The remaining measurements did not show any noticeable trend relative to depth. The plastic limit was not obtainable because the samples were coarse grained. As a result, the plasticity index, liquidity index, and activity values could not be computed. By Shepard's trilineal classification plot, the sediments had classifications in the sand, clayey sand, and silty sand groups. Sand constituted between 64% and 81%, silt between 9% and 18%, and clay between 10% and 18% (by weight) of the sediments. Specific gravity of solids ranged from 2.608 to 2.843. Median diameters ranged from 0.068 to 0.214 mm.

<sup>\*</sup>F. F. Wright, Marine Geology of San Miguel Gap, Off Point Conception, California. Ph D Dissertation, Department of Geology, University of Southern California (in preparation).

The glauconite-abundant samples (MH-1, 2, 3, and 4) possessed some physical properties differing from those of the quartz-abundant samples MH-5, 6, and 7. The average median diameter and specific gravity for the first group of samples were 0.118 mm and 2.752, respectively. For the second group, the average median diameter and specific gravity were 0.076 mm and 2.716, respectively. The glauconite-abundant samples had a smaller average carbonate content (10.59%) than the quartz-abundant samples (15.77%). A relationship may exist between glauconite formation and foraminifera activity.

There appears to be a zone of minimum carbonate in some of the samples that may be significant geologically. This zone is located approximately 15 inches from the sediment surface. The specific gravity values tend to increase in this zone, which is as expected, since carbonates in the form observed in the microscopic analysis have lower specific gravities than glauconite and quartz. Since these carbonates are at a minimum in this zone, the average specific gravity would therefore be higher.

#### Foundation Analysis

Assuming that ocean-floor sediments can be treated as submerged terrestrial soils, the concepts of foundation analyses used for terrestrial soils were applied in this study. Since the health and welfare of personnel were not dependent on the stability of the structure and its foundation, and because the total cost of the STU was not great, a detailed foundation analysis was not warranted. A very brief analysis was made to determine the stability of the foundation.

The proposed submersible test units had the following characteristics:

Weight - STU II-1: 7,350 pounds (in air) STU II-2: 8,750 pounds (in air)

Footing - Two plates: 3 feet 2 inches by 12 feet 6 inches

Depth of footing below sediment surface -0 feet

The ultimate bearing capacity of the soil  $(p_{max})$  was calculated using the equation presented by Tschebotarioff: <sup>16</sup>

$$p_{\text{max}} = 5.52c \left( 1 + 0.38 \frac{h}{b} + 0.44 \frac{b}{L} \right)$$
 (1)

1

where c = cohesion

h = depth of footing below soil surface

b = breadth of footing

L = length of footing

It should be noted that this equation considers the soil to be entirely cohesive; that is, the angle of internal friction is zero. An average value of cohesion, obtained using the vane shear technique, was used in this analysis. This approach was used because the sediments at the site were soft and could not be routinely evaluated using direct shear or triaxial testing procedures. Additionally, sample disturbance received during coring does not justify such elaborate shear strength measurements. Sample disturbance has been discussed in greater detail by Inderbitzen. 17

The applied stress due to the weight of the STU was 110 pounds per square foot. The ultimate bearing caracity of the supporting sediments according to Equation 1 was 300 pounds per square foot and, therefore, a factor of safety in bearing of approximately 3 existed.

Å settlement analysis was made using the data presented herein and methods outlined by Hough, <sup>18</sup> and Terzaghi and Peck. <sup>13</sup> A plot of void ratio versus effective stress (Figure 7) was developed using compression indexes computed as previously discussed. The solid lines on Figure 7 are e log p curves drawn for the limiting values of void ratios and compression indexes. The dashed line indicates the compression index and the corresponding void ratios which were used for this analysis. This compression index was selected to compensate for the low crushing strength of the glauconite grains. It is interesting to note that the minimum void ratios determined by this method correspond well with those suggested by Hamilton. <sup>19</sup> The analysis was made assuming that significant compressions occur only within the soil layer extending from footing grade to the level at which the effective applied stress equals 10% of the effective overburden stress. The distributed effective applied stress was calculated using the 60-degree approximation method described by Hough: <sup>18</sup>

$$\Delta p = \frac{A_1}{A_2} \Delta p_f$$

where  $\Delta p$  = change in effective stress due to the applied load

 $A_1$  = area of footing

 $A_2$  = area at depth Z

Z = depth below footing grade

 $\Delta p_f$  = bearing pressure at footing grade due to the applied load = 110 psf

The applied effective stress at any depth, Z, expressed in terms of the dimensions of the STU and the bearing pressure at footing grade is:

$$\Delta p = \frac{(3.167)(12.5)(110)}{(3.167 + Z)(12.5 + Z)} \tag{2}$$

#### According to the assumptions

$$\Delta p = (0.1) \gamma' Z \tag{3}$$

where  $\gamma'$  = submerged unit weight of the sediment. Solving Equations 2 and 3 simultaneously, the depth of significant stress was determined to be 5.8 feet. An estimate was made of the total settlement within this depth using the following equations:

$$\Delta H_{i} = H \frac{C_{c}}{1 + e_{c}} \log \left(1 + \frac{\Delta p}{p_{c}}\right)$$
 (4)

$$S = \sum_{i=1}^{n} \Delta H_{i}$$
 (5)

where  $\Delta H_i$  = change in thickness of layer

H = initial layer thickness

C = compression index

e = initial void ratio

 $\Delta p$  = change in effective stress due to the applied load

p = initial effective stress

S = total settlement

n = number of layers

The total settlement was computed to be 1.7 inches. This calculated settlement is not excessive and is tolerable for this type of structure. In most foundation analyses for ocean floor structures, as in this analysis, settlement considerations rather than bearing capacity of the supporting sediments will govern the design because pelagic sediments are usually highly compressible, normally consolidated clays. In recent research on consolidation characteristics of pelagic sediments, Nielsen<sup>20</sup> discusses this in greater detail.

The actual total settlements of the structures were determined from mudline markings on the material specimens exposed to the sediment environment. These specimens extended 6 inches below the bottom of the bearing plates. On STU II-1, the mudline markings on the specimens ranged from zero to 8 inches. For this STU the total maximum settlement was approximately 2 inches, which compares favorably

with the calculated value of 1.7 inches. On STU II-2, the mudline markings ranged from 1/4 inch to 6 inches. The total settlement was negligible in this case. From markings on the specimens on both STUs, it appears that either the ocean floor was very irregular or that scour or fill occurred. It was not readily apparent if the structures were subjected to differential settlements.

#### Statistical Evaluation of Test Data

In the future, as activity in the deep ocean environment increases, the need for site reconnaissance and selection information on specific ocean floor areas will be required. In anticipation of this need, the test results from the cores were analyzed statistically to determine if there were any significant correlations between (1) vane shear strength and bulk wet density and (2) the various laboratory measured properties of the samples. It is expected that these correlations will be used in making bearing capacity and settlement estimates in site reconnaissance and selection studies. For example, it may become necessary to determine values for vane shear strength of a core sample taken for other purposes and tests or which has desiccated from long storage. Also, as in-situ testing procedures progress at NCEL and other activities, it will be necessary to correlate bulk wet density values with in-situ test values. For example, settlement estimates may be required for a specific ocean floor site from which in-situ vane shear values are available. By the use of the correlation, estimates of bulk wet density may be made to be used in calculating settlement estimates.

By using a stepwise regression analysis procedure, 21 two separate linear regression analyses were conducted. The first analysis was made to determine the relationship between vane shear strength and the various index and measured properties. The second analysis was made to determine similar relationships for bulk wet density. It was found that vane shear strength was dependent on depth below the sediment surface, liquid limit, and median diameter of the sediment. Bulk wet density was dependent on vane shear strength and sensitivity. Although these analyses were based on laboratory measured values, it is believed that these relationships are also valid for in-situ values. Later, as in-situ vane shear data become available, the relationship between laboratory measured and in-situ measured vane shear values can be validated.

The equation derived for the vane shear strength is:

$$VSS = k_1(D) + k_2(LL) + k_3(MD) + k_4$$
 (6)

1

where VSS = vane shear strength, psi

D = depth in sediment, in.

LL = liquid limit, %

MD = median diameter, mm

 $k_n = constants (n = 1, 2, 3, 4)$ 

The values computed for kn for this set of data are

$$k_1 = 2.34 \times 10^{-2}$$
  $k_3 = 1.43 \times 10^{-1}$   
 $k_2 = -2.72 \times 10^{-3}$   $k_4 = 3.64 \times 10^{-1}$ 

In Figure 8 the calculated vane shear strength using the above equation and constants is shown plotted against the measured vane shear strength. The points are somewhat dispersed about the 45-degree line; however, there is a definite direct correlation between the measured and calculated values.

The substitution of the constants into the equation, however, does not give a general equation which can be used for all ocean floor areas. Therefore, the problem at the moment is to determine the values for the constants  $k_n$  for given bottom terrain areas. One solution would be to use four equations with different values for the constants  $k_n$  to represent the four general terrain types of the ocean bottom which can be classified as the continental shelf, continental slope, low rise, and basin areas.

It must be noted that sampling technique (e.g., the use of a piston) and coring apparatus characteristics (e.g., area ratio of cutting nose<sup>3</sup> and the inside diameter of the sampler), will affect the constants  $k_n$ . Once the influence of the sampling technique and the sampler characteristics on the constants is determined, the four equations can be derived with sufficient data from the four terrain types.

The equation derived for bulk wet density is in the form

$$BWD = c_{1}(VSS) + c_{2}(SN) + c_{3}$$
 (7)

where BWD = bulk wet density, gm/cc

VSS = in-situ vane shear strength, psi

SN = in-situ sensitivity

 $c_n = constants (n = 1, 2, 3)$ 

For this particular set of data, the values computed for c<sub>n</sub> are

$$c_1 = 9.87 \times 10^{-2}$$

$$c_2 = -5.71 \times 10^{-2}$$

$$c_3 = 1.843$$

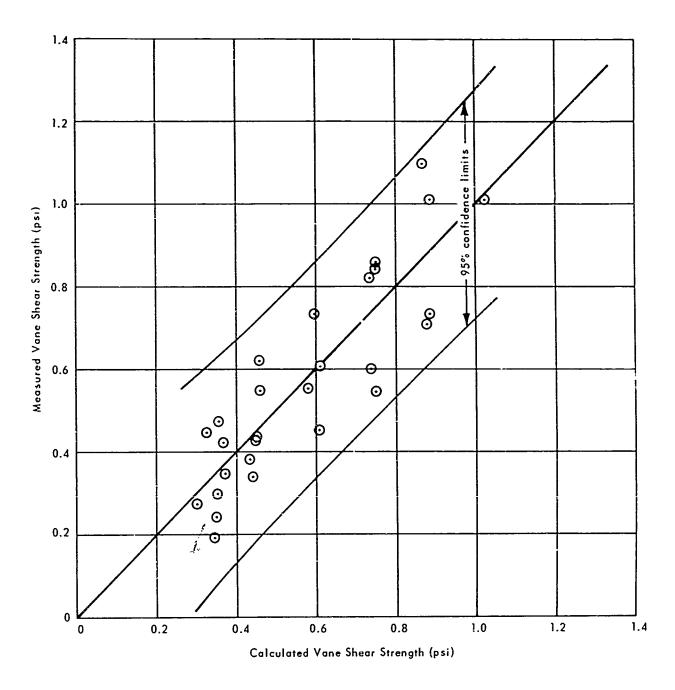

Figure 8. Measured versus calculated vane shear strengths, core MH-1 to MH-8.

In Figure 9 the calculated bulk wet density using the above equation and constants is shown plotted against measured laboratory bulk wet density. There is a definite direct correlation between the measured and calculated values.

Substitution of the constants  $c_n$  in the equation will not give a general equation that can be used for all ocean floor areas. Again, as in the equation predicting vane shear strength, the problem is to determine the values of the constants  $c_n$  accurately. Four equations could be developed for the four terrain types discussed previously; the four resulting values for each of the constants would be applicable to the respective types. As in the previous equation, the factors that would possibly have influence on the constants may be the sampling technique, sampler characteristics, and testing technique. In addition, the relationship between in-situ and laboratory vane shear values must be established. Once the influence of the factors is determined, the desired equations can be derived with sufficient data from the four terrain types.

The correlation of the various properties with shear strength and bulk wet density is presented here as a possible technique to predict these values when only a few index properties and characteristics are known. The equations presented should not be used indiscriminately because they are applicable only to a very limited area and conditions. These equations are presented to illustrate the technique as a possible method of predicting the values for vane shear strength and bulk wet density. The analysis, however, satisfactorily establishes the relationship between (1) vane shear strength and bulk wet density and (2) their respective independent variables. Upon establishing the values for the constants, these equations could be used for site selection and reconnaissance surveys.

It should not be construed that detailed site investigation, soil testing, foundation design, and analysis could in any instance be replaced by the results of these statistical procedures. If an engineering structure is to be founded on a specific location, that particular location must be investigated and analyzed for its own merits. However, the preliminary studies on the proposed areas of interest could be partially accomplished using the method presented here.

#### **FINDINGS**

1. In the foundation analysis, the bearing capacity of the supporting sediments was adequate and the total settlement was tolerable. The calculated average bearing capacity of the supporting sediments was 300 pounds per square foot. The applied load from the STU was approximately 110 pounds per square foot at the base of the footing. The computed total settlement was 1.7 inches. The actual settlements as observed from the mudline markings on material test specimens were approximately 2 inches for STU II-1 and negligible for STU II-2.

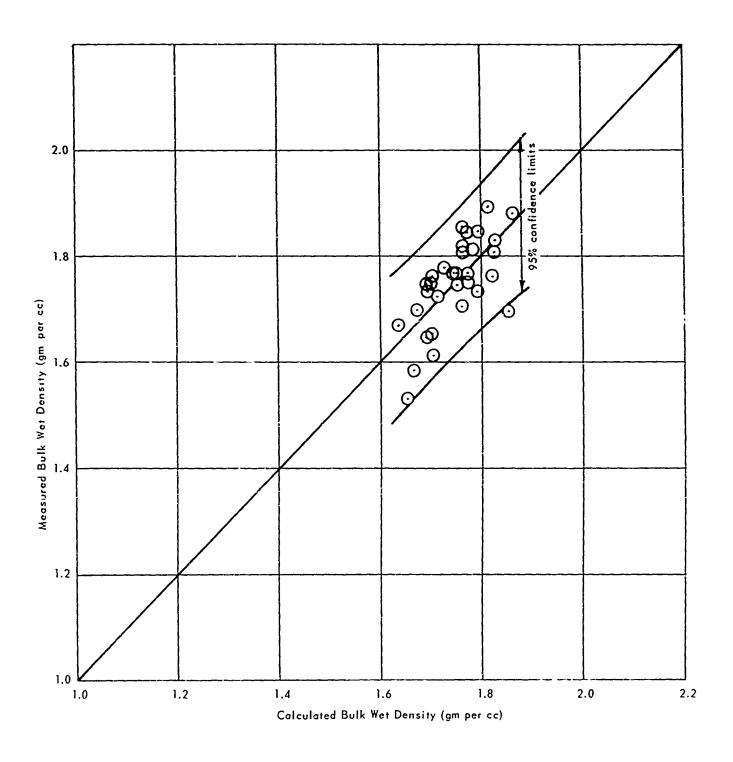

Figure 9. Measured versus calculated bulk wet density, cores MH-1 to MH-8.

2. Some of the sediment properties pertinent to the stability of the structure at the site investigated were:

Sediment Properties	Average	Range
Bulk wet density, gm/cc	1.749	1.530 to 1.895
Vane shear strength, psi	0.650	0.196 to 1.459
Sensitivity	2.8	1.6 to 4.0
Water content, %	46.2	34.7 to 71.5
Specific gravity of solids	2.740	2.608 to 2.843
Void ratio	1.300	0.969 to 1.941
Liquid limit, %	35.5	28.4 to 49.1
Compression index	0.23	0.18 to 0.35
Carbonate content, %	12.78	1.53 to 23.36
Organic content, %	1.35	0.86 to 2.14

In general, the sediments are coarse grained with classifications in the sand, clayey sand, and silty sand groups. Glauconite and quartz were the primary constituents in the plus-325-mesh fraction.

The values for bulk wet density, vane shear strengths (undisturbed and remolded samples), and dry density increases with depth in the sediment column. Sensitivity, water content, void ratio, porosity, and saturated void ratio are inversely proportional to depth in the sediment column. A layer of pebbles was present at the base of core samples MH-2 and AH-4 that would have an influence on the stability of the structure.

3. The statistical study shows that (1) vane shear strength is a function of depth below the sediment surface, liquid limit, and median diameter; and (2) bulk wet density is a function of vane shear strength and sensitivity.

For this area and particular sediment type, the vane shear relationship is

$$VSS = 0.0234(D) - 0.00272(LL) + 0.143(MD) + 0.364$$

The relationship for bulk wet density for this area and sediment type is

$$BWD = 0.0987 (VSS) - 0.0571 (SN) + 1.843$$

#### CONCLUSION

The techniques employed in the foundation analysis in this study provided a reasonable estimate of bearing capacity and settlement. The statistical procedures presented can be used to develop equations to predict vane shear strength and bulk wet density for site reconnaissance and site selection purposes.

REMARKS						

THIS CORE IS COMPOSED OF SANDY CLAY. SAND IS MOST ABUNDANT AT THE TOP, POSSIBLY REFLECTING WINNOWING AT THE SURFACE. SAND-SIZED FRAGMENTS ARE MAINLY GLAUCONITE WITH SOME QUARTZ. THE PRESENCE OF GLAUCONITE INCREASES THE PROBABILITY OF WINNOWING. THERE ARE PROMINENT MODERATE OLIVE BROWN (5Y4/4) MOTTLES IN A MATRIX OF OLIVE GRAY (5Y3/2) SEDIMENT. LARGE BENTHONIC FORAMINIFERA VISIBLE IN THE CORE. PLANKTONIC FORAMINIFERA IN COARSE FRACTION ANALYSES.

REMARKS						

MODERATE OLIVE BROWN (5Y4/4) WITH SLIGHTLY LIGHTER (5Y5/6) MOTTLES OR DISTORTED BEDS. CORE RETAINER DRAGGED EDGES OF BEDS DOWNWARD. VERY SANDY ON SURFACE, LARGELY GLAUCONITE, BECOMING LESS SO DOWNWARD. SAND-SIZED GRAINS ARE LARGELY GLAUCONITE. ELLIPTICAL MOTTLES LOOK LIKE WORM TUBES FILLED WITH DARKER (REDUCED) SEDIMENT.

13. ARSTRACT	<u> </u>				

In April 1964 study was begun of the ocean floor at the proposed site for emplacing Submersible Test Unit II (STU II) series to determine whether the floor would provide a suitable foundation for the STUs. Eight sediment cores were taken to determine the engineering properties of the sediments in an area approximately 2 miles square in the vicinity of 34° 05.5'N, 120° 43.0'W, some 14 miles west of San Miguel Island, California. In addition, a bathymetric chart of the area was constructed using data from the precision depth recorder and navigational instruments aboard the USS Molala. Laboratory tests were conducted on core samples and computations of bearing capacity and settlement were made for the area with the resulting data. The calculated average bearing capacity was 300 pounds per square foot. The applied load of the STU was approximately 110 pounds per square foot. The calculated total settlement was 1.7 inches.

The test results were analyzed statistically to determine the relationships (1) between vane shear strength and depth below the sediment surface, liquid limit, and median particle diameter; and (2) between bulk wet density and vane shear strength and sensitivity. The results indicate the correlations are satisfactory for use in site reconnaissance and site selection studies.

## INSTRUCTIONS

- 1. ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (corporate author) issuing the report.
- 2a. REPORT SECURTY CLASSIFICATION: Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.
- 2b. GROUP: Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.
- 3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.
- 4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.
- 5. AUTHOR(S): Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.
- 6. REPORT DATE. Enter the date of the report as day, month, year, or month, year. If more than one date appears on the report, use date of publication.
- 7s. TOTAL NUMBER OF PAGES: The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.
- 7b. NUMBER OF REFERENCES: Enter the total number of references cited in the report.
- 8a. CONTRACT OR GRANT NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.
- 8b, 8c, & 8d. PROJECT NUMBER: Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.
- 9a. ORIGINATOR'S REPORT NUMBER(S): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.
- 9b. OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers (either by the originator or by the sponsor), also enter this number(s).
- 10. AVAILABILITY/LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those

imposed by security classification, using standard statements such as:

οž

THE PARTY OF THE P

- (1) "Qualified requesters may obtain copies of this report from DDC."
- (2) "Foreign announcement and dissemination of this report by DDC is not authorized."
- (3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through
- (4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through
- (5) "All distribution of this report is controlled. Qualified DDC users shall request through

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

- 11. SUPPLEMENTARY NOTES: Use for additional explanatory notes.
- 12. SPONSORING MILITARY ACTIVITY: Enter the name of the departmental project office or laboratory sponsoring (paying for) the research and development. Include address.
- 13. ABSTRACT: Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS), (S), (C), or (U).

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14 KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, rales, and weights is optional.
